

Why these nulls are weak evidence, not strong negatives

Pooling the three resistance-context datasets (random-effects meta-analysis), 0 of 13 screen hits met the criteria. The smallest is 0.100 (USP34). GSE111151 — the only dataset with several independent resistance contexts — could detect a 1.5-fold change at 80% power, and all 12 of its testable candidate effects were small. *Its nulls are uninformative, not negative. The power argument applies to GSE111151; the other nulls are weak evidence.*
