

Orthogonal validation distinguishes tamoxifen-specific sensitisation (panel A / Figure F1) from baseline cell-line essentiality (panel B). High baseline dependency (TLK2) is not automatically an advantage -- it may reflect a narrower, less tamoxifen-specific therapeutic window, exactly as for VEZF1's more moderate dependency. KDM1A shows low baseline dependency despite the strongest CRISPR sensitisation signal (Figure F1), the clearest tamoxifen-specific-vs-baseline dissociation among the four focus genes.
