

A. Sensitisation strength is not the same axis as baseline dependency

B. Distinct candidate roles and proposed follow-up logic (no universal winner)

KDM1A Strongest functional benchmark: rank 1/13 by CRISPR effect and FDR; existing clinical-stage LSD1 pharmacology (e.g. iadademstat). Low baseline dependency. <i>Follow-up: LSD1-inhibitor combination assay (tamoxifen +/- iadademstat)</i>	TLK2 Strongest baseline dependency among the 4 focus genes (81.8% of 11 lines) -- a real experimental kinase structure exists, but no selective inhibitor. <i>Follow-up: baseline-dependency vs. tamoxifen-specific rescue assay</i>	USP34 Structurally tractable novel lead: covalent catalytic-cysteine (Cys1903) reactivity demonstrated; no validated inhibitor yet; not the top CRISPR hit (rank 12/13). <i>Follow-up: covalent-probe engagement assay; CRISPR-competition validation</i>	VEZF1 Strongest recurrence-associated human signal (GSE240112, single dataset) among the 4 focus genes; hard-to-drug zinc-finger transcription-factor class. <i>Follow-up: recurrence-cohort replication; CRISPR-competition validation</i>
